- PhD Advisor: Chris Rycroft

Introduction

The Asteroid Search Problem

- Many asteroids (about 958,000 known) in the Solar System
- We want to learn their orbits
- Biggest data source: telescope detections
- Easy once you know which detection matches which asteroid
- This is like a jigsaw puzzle with millions of pieces!

This puzzle is too hard even with the COVID-19 Lockdown

Combining Tracklets vs. Orbital Element Search

- "Tracklet": two detections close to each other in time and direction
- Existing search methods: greedy search over tracklets
- Drawbacks: Myopic, Combinatorial Explosion
 - Myopic can only connect detections made close in time
 - Suffers from combinatorial explosion
- Proposed novel method: search Orbital Elements
 - 6D space; large, but scales well
 - Cost scales as $N_{\rm ast} \cdot N_{\rm obs}$ rather than $N_{\rm obs}^r$

Search Overview

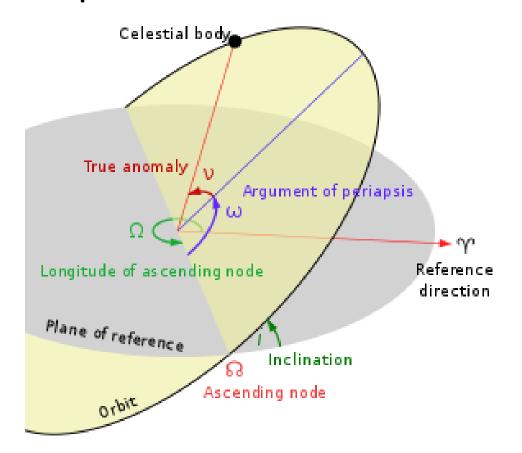

- Initialize candidate orbital elements a, e, i, Ω , ω , f
- Mixture parameters: N_h , R, τ
- Compute position q and velocity v from candidate elements
- Compute direction \mathbf{u}_{pred} from \mathbf{q} , \mathbf{v} ; include light time and topos
- Compute distance s from \mathbf{u}_{pred} to \mathbf{u}_{obs} for ZTF observations
- Compute log likelihood \mathcal{L}_i for each candidate element
- Gradient descent...
- The rest is details! Which you will now hear all about...

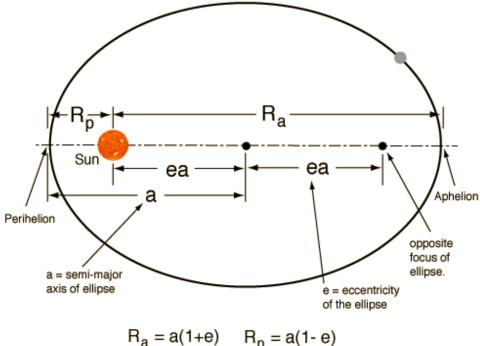

Integrating the Solar System

REBOUND Integrator for N-Body Problem

- REBOUND is a modern, open source integrator
 - It numerically solves the gravitational N-body problem
 - Considered the "gold standard" for orbits in this work
 - IAS15 adaptive integrator uses Gauss-Radau quadrature and a "predictor-corrector" scheme
 - github.com/hannorein/rebound and PyPI
- Horizons: API provided by NASA JPL to obtain state vectors (position and velocity) of objects in the Solar System
 - Considered "gold standard" for initial conditions of an integration

Keplerian Orbital Elements

 $R_a = a(1+e)$ $R_p = a(1-e)$

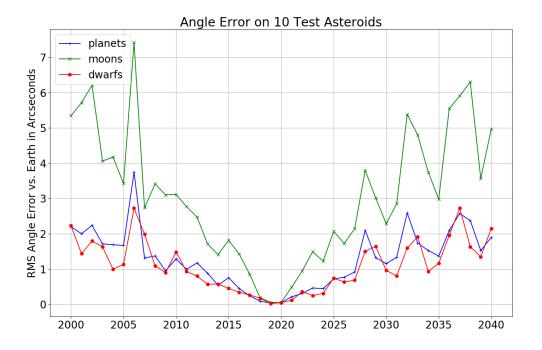

Image Credits: WikiPedia, Cool Cosmos

- Semi-major axis a and eccentricity e describe the size and shape of the orbital ellipse
- Inclination i, ascending node Ω , perihelion ω are angles orienting orbit in the ecliptic plane
- True anomaly f is location of the body on its orbital ellipse

Validating Integration vs. Horizons

- Integrate three massive body collections and asteroids
- Error metrics: position in (AU) and instantaneous angle from asteroid to Earth (arc seconds)
- Accuracy is excellent!
 - RMS error on planets is 5.4E-6 AU
 - Angle error from asteroids to planets 0.8 arc seconds

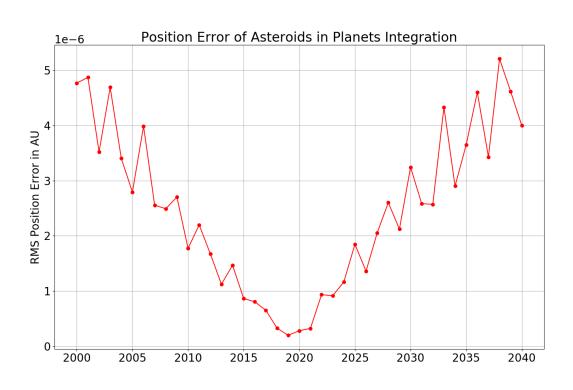

Bulk Integration of 733,489 Asteroids

733489 rows × 19 columns 11

Validate Asteroid Integration vs. Horizons

- Test bulk asteroid integration on first 25 IAU asteroids
- Excellent results! RMS 2.49E-6 AU and 0.45 arc seconds

Integrate Kepler Two Body Problem in TensorFlow

- Analytical solution to Kepler problem is an ellipse
- 5 of the 6 orbital elements a, e, i, Ω , ω constant
- The Mean Anomaly M is linear in time (2nd Law)

$$M(t) = M_0 + N \cdot (t - t_0)$$

• Kepler's Equation relates orbital anomalies:

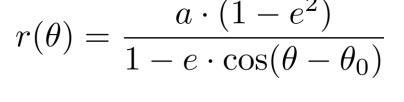

$$M = E - e\sin(E)$$

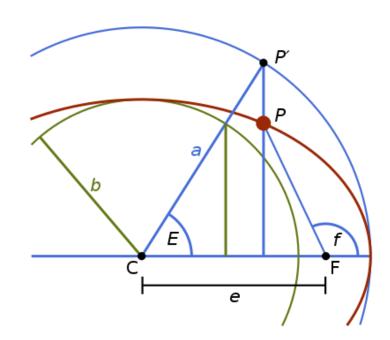

Kepler's Equation

$$\tan\left(\frac{f}{2}\right) = \sqrt{\frac{1+e}{1-e}} \cdot \tan\left(\frac{E}{2}\right)$$

true to eccentric

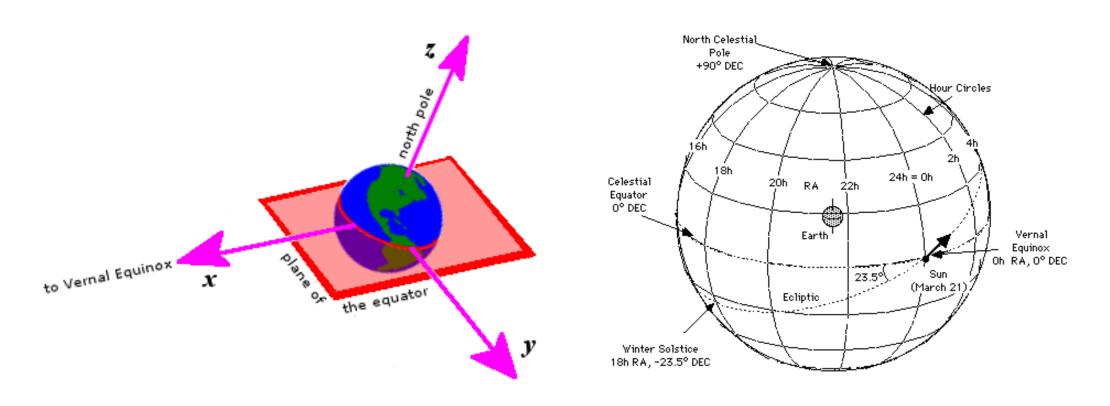

- Convert *M* to *E* to *f*, then to Cartesian coordinates
- TensorFlow is fast! 5000 time points in ~300 μ sec
- Apply calibration dq, dv to match REBOUND integration at input orbital elements

Predicting Directions from Positions

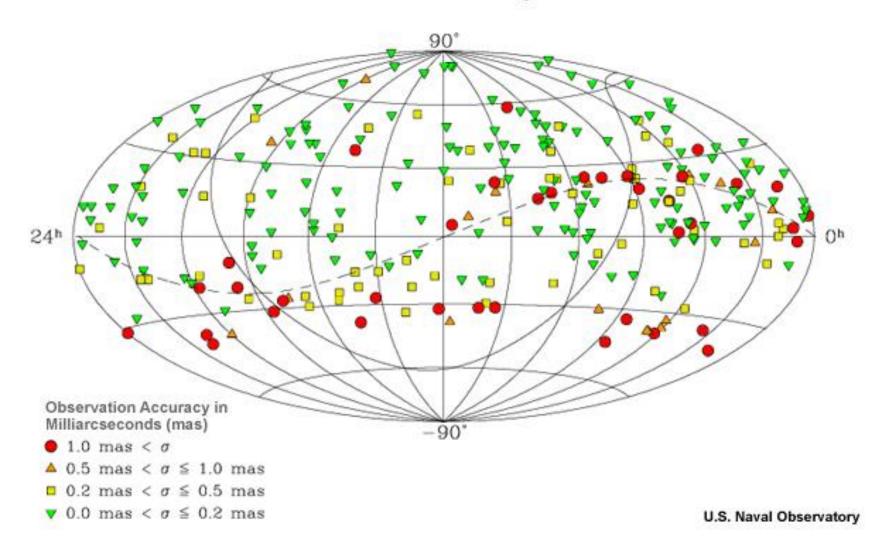

Right Ascension and Declination

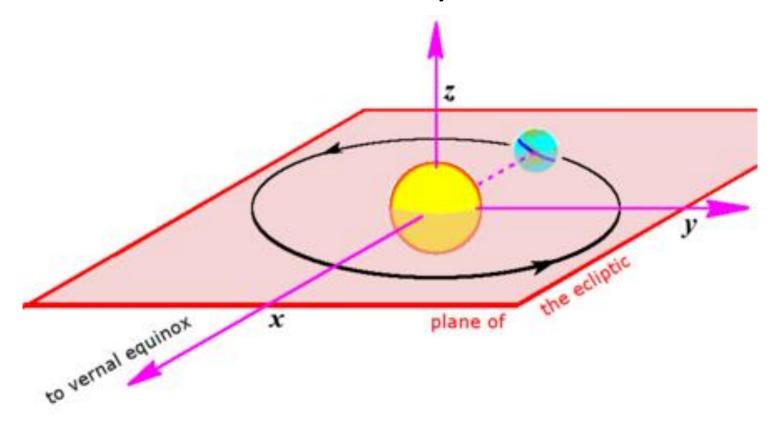

- Fundamental plane is aligned with Earth's equator
- Intuitive, dates to ancient astronomers
- Two problems: precession (drift) and nutation (wobbles) in direction of North Pole

International Celestial Reference Frame (ICRF)

The Celestial Reference Frame Observed by Radio Waves at 24 GHz

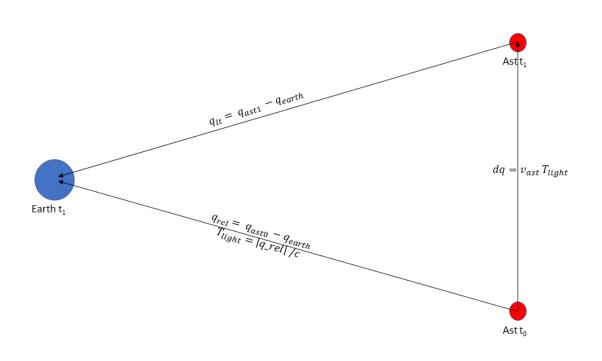

From RA/Dec to Barycentric Mean Ecliptic

Convert between ICRF and BME using astropy library:
 obs_icrs = astropy.SkyCoord(ra=ra, dec=dec, obstime=obstime, frame=ICRS)
 obs_ecl = obs_icrs.transform_to(BarycentricMeanEcliptic)

Calculate Direction from Position and Velocity

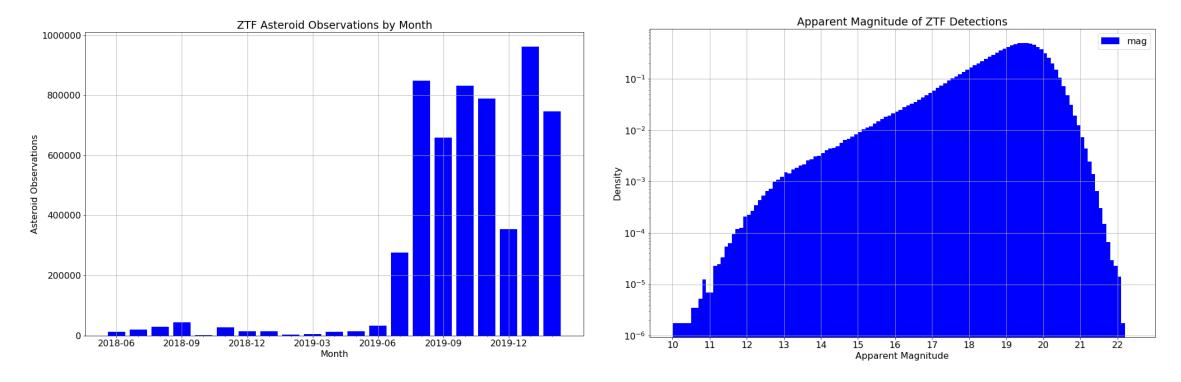

- Need to remember light speed c is finite!
- Otherwise wrong by ~285 arc seconds

$$\mathbf{q}_{\mathrm{rel}} = \mathbf{q}_{\mathrm{ast}} - \mathbf{q}_{\mathrm{earth}}$$
 $T_{\mathrm{light}} = \|\mathbf{q}_{\mathrm{rel}}\|/c$
 $\Delta \mathbf{q}_{\mathrm{ast}} = \mathbf{v}_{\mathrm{ast}} \cdot T_{\mathrm{light}}$
 $\mathbf{q}_{\mathrm{lt}} = \mathbf{q}_{\mathrm{rel}} - \Delta \mathbf{q}_{\mathrm{ast}}$
 $\mathbf{u} = \mathbf{q}_{\mathrm{lt}}/\|\mathbf{q}_{\mathrm{lt}}\|$

- Also need "topos adjustment" for observatory: Palomar Mountain, not geocenter!
- Topos adjustment worth 0-5 arc seconds on first 16 asteroids
- Validated these calculations vs. JPL and SkyField

Analysis of ZTF Asteroid Detections

EDA of ZTF Detections

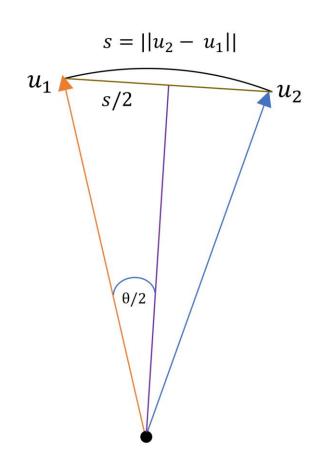

- ZTF: Zwicky Transient Facility; survey of northern sky at Palomar Mountain by Cal Tech
- Data includes: MJD, RA, DEC, MAG
- 5.69 million possible asteroid detections used for masters thesis in May 2020
- Update: As of March 2021 now have ~158 million asteroid detections in a database!

Converting Cartesian to Angular Distance

- How far apart are two directions in the sky?
- Convert RA/Dec to directions u₁ and u₂ in the BME
- Compute Cartesian distance s between u₁ and u₂
- Angular distance θ is geodesic (great circle distance)

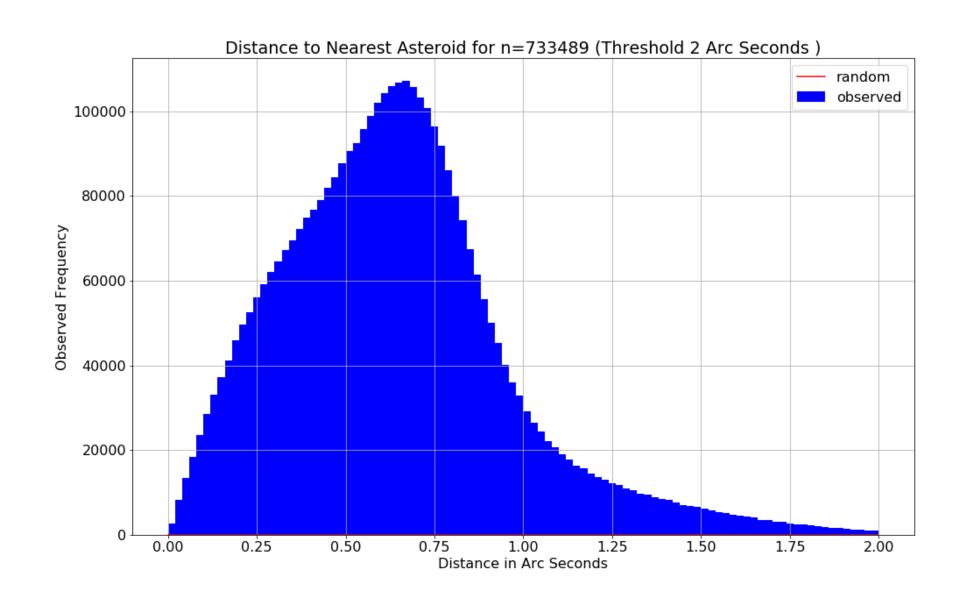

$$\sin(\theta/2) = s/2$$

Nearest Asteroid to Each ZTF Detection

- Compute direction $u_{obs} = (u_x, u_y, u_z)$ from RA/Dec for each detection
- Compute direction u_{ast} for every asteroid in the catalogue
- 5.7E6 detections x 7.3E5 asteroids = 4.2E12 (4.2 trillion) interactions!
 - "Only" 97,111 different MJDs with ZTF detections
- Perform reduction operation on chunks of 1000 asteroids
 - Completes in 25 hours on 40 CPUs

Nearest Asteroid: 65.7% Within 2.0 Arc Seconds!

Statistical Distribution of Distance on Sphere

 What is the statistical distribution of s if we guessed directions uniformly at random?

$$s^2 = 2 \cdot (1 - z)$$
 $z = 1 - s^2/2$

- This is useful parameterization because...
- "Orange Slicing Theorem" for solid angle measure:

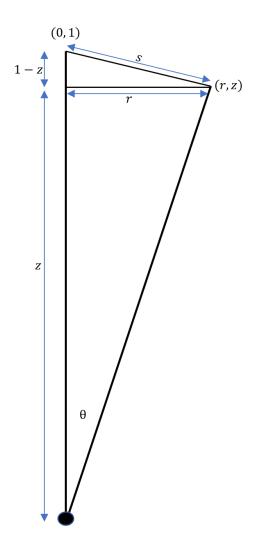

$$d\Omega = dz \cdot d\phi$$

• Think of Z and S as random variables:

$$Z \sim \text{Unif}(-1,1)$$
 $S^2 \sim \text{Unif}(0,4)$

ullet Conditional on a max (threshold) distance τ

$$S^2|S \le \tau \sim \text{Unif}(0,\tau^2)$$

Distribution of Nearest Asteroid Distance

Set a threshold distance τ and define relative squared distance V

$$V = (S/\tau)^2$$
 $V \sim \text{Unif}(0,1)$

• We have n = 733,489 guesses and are picking closest

$$V_1, \dots V_n \stackrel{i.i.d.}{\sim} \text{Unif}(0,1)$$

• Stat 110: The minimum of n i.i.d. uniforms has a Beta distribution

$$U_{(1)} \sim \text{Beta}(1, n)$$

- How many hits at 2.0 arc seconds would we get by luck?
- Only 98. But we got 3.75 million of them!
- Conclusion: This whole apparatus works to a tolerance of 2.0 arc seconds

Asteroid Search Using Orbital Elements

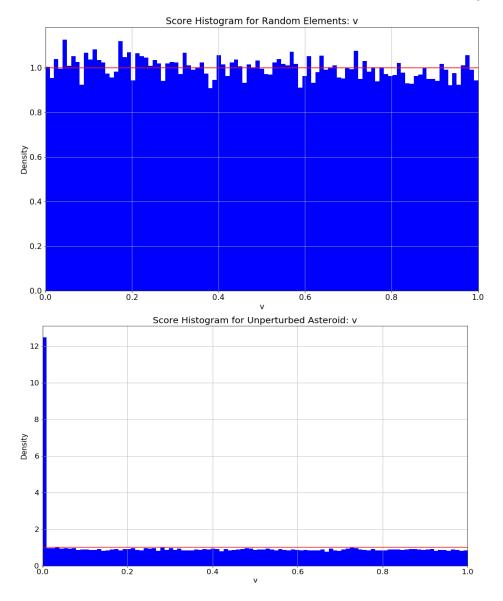

Assemble ZTF Detections Near Elements

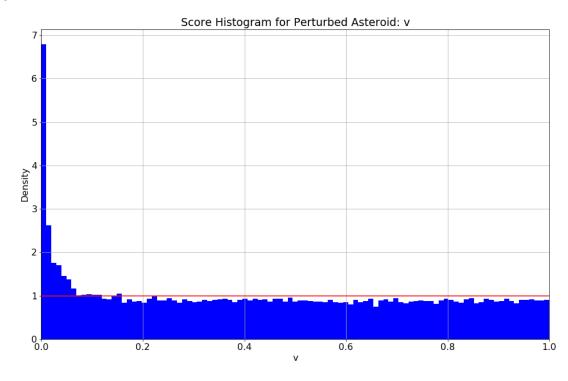

```
# Load unperturbed element batch
ztf elt ast = load ztf batch(elts=elts ast, thresh deg=1.0, near ast=False)
# Review
ztf elt ast[cols]
       element id
                     ztf id
                                    mid
                                                           dec
                                                                                                           elt ux
                                                                                                                     elt uy
                                                                                                                               elt uz
                                                                                                                                                         v is hit
                                                                      ux
                                                                                              mag app
                                                                                                                                            s sec

```

90211 rows × 15 columns

- Integrate the candidate elements on the fly in REBOUND and compute directions
- Filter the ZTF detections to those within threshold of the elements

Distribution of $V = (S/\tau)^2$ for 3 Element Batches

- Plot V for 3 batches: random, unperturbed, perturbed
- Results match theory perfectly!
- Random elements close to uniform distribution
- Unperturbed: uniform on misses with spike in first bucket
- Perturbed: in between; hits leak out to ~250 arc seconds

Log Likelihood Objective Function

• Mixture probability model: V mixture of h hits, (1-h) misses

$$V|\mathrm{Hit} \sim \mathrm{Expo}(\lambda)$$
 $V|\mathrm{Miss} \sim \mathrm{Unif}(0,1)$

• Relate decay rate to "resolution" parameter R $f(v) \propto e^{-\lambda v} = e^{-\lambda s^2/\tau^2} \qquad f(v) \propto e^{-s^2/2R^2} \qquad \lambda = \frac{\tau^2}{2R^2}$

- The resolution R controls how tightly the model focuses
- Mixture PDF:

$$h \cdot \frac{\lambda \cdot e^{-\lambda v}}{1 - e^{-\lambda}} + (1 - h)$$

• Log Likelihood:

$$\mathcal{L}(\mathbf{v}, h, \lambda) = \sum_{j=1}^{n} \log \left(h_j \cdot \frac{\lambda \cdot e^{-\lambda_j v_j}}{1 - e^{-\lambda_j}} + 1 - h_j \right)$$

Search Overview: (Should Look Familiar)

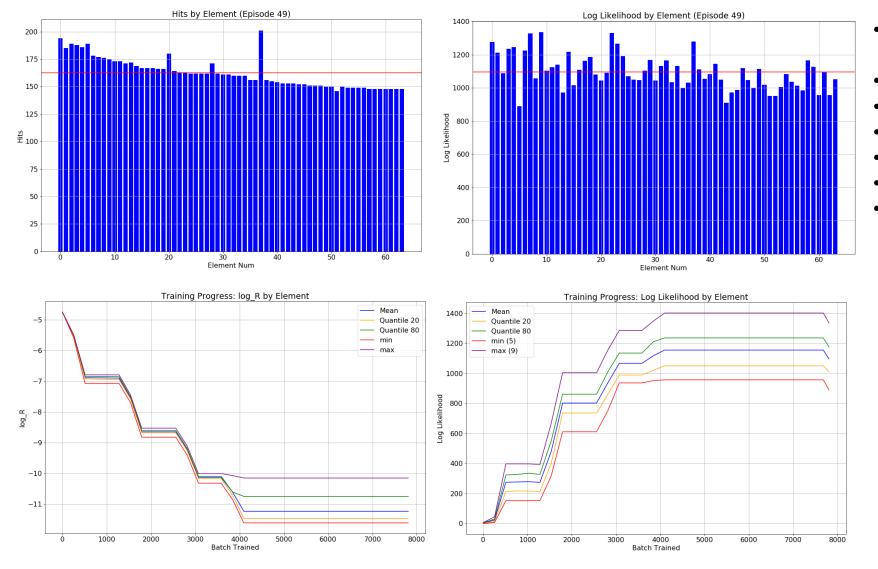

- Six trainable orbital elements a, e, i, Ω , ω , f; epoch not trainable
- Three trainable mixture parameters: N_h , R, τ
- Compute position q and velocity v from candidate elements
- Compute direction \mathbf{u}_{pred} from \mathbf{q} , \mathbf{v} ; include light time and topos
- Compute distance s from \mathbf{u}_{pred} to \mathbf{u}_{obs} for ZTF observations
- Compute log likelihood \mathcal{L}_i for each candidate element
- Gradient descent...
- The rest is details!

Asteroid Search Results

Comparing Two Orbital Elements

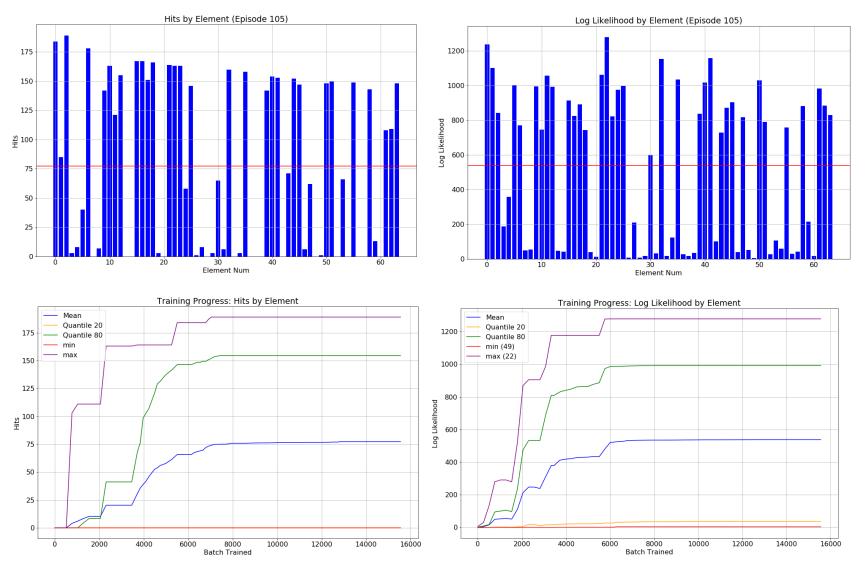

- How far apart are two 6D orbital elements ε_1 and ε_2 ?
- A naïve Euclidean norm makes no sense at all
- Idea 1: Inject the elements into space at a set of times
- Idea 2: Transform elements into low dimensional Cartesian space

Train Known Asteroid Elements: Unperturbed

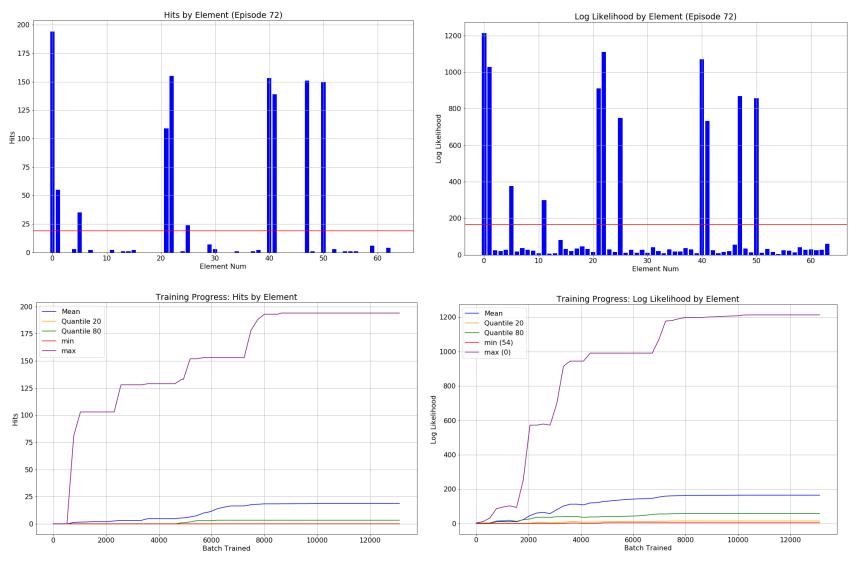

- Start with correct elements but uninformed mixture parameters
- Convergence is almost perfect
- Recovered Elements: 64 (100%)
- Hits: 162.6
- Resolution: 3.0 arc seconds
- Log Like: 1097
- Fit quality excellent: 4.6E-8 AU

Train Known Asteroid Elements: Small Perturbation

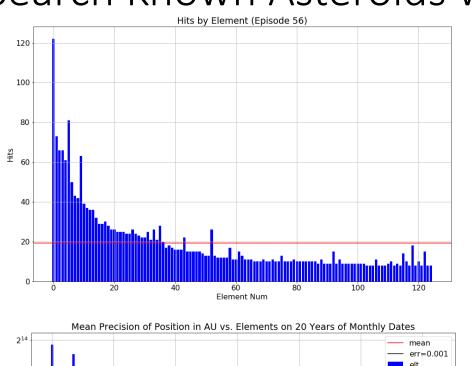

- Small perturbation:
 - 1.0% to a
 - 0.25% to e
 - 0.05 degrees to *i*
 - 0.25 degrees to Ω , ω , f
 - Convergence is very good
- Recovered Elements: 42 (65.6%)
- Hits: 117.5
- Resolution: 18.2 arc seconds
- Log Like: 798
- Fit quality decent: 2.6E-4 AU
- Challenge: get full convergence

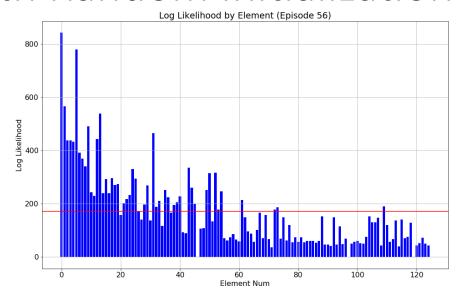

Train Known Asteroid Elements: Large Perturbation

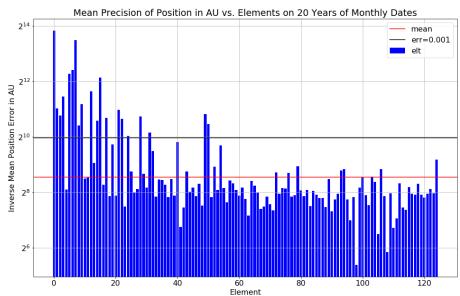

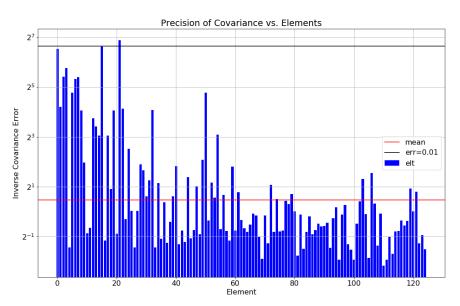

- Small perturbation:
 - 5.0% to a
 - 1.0% to *e*
 - 0.25 degrees to *i*
 - 1.0 degrees to Ω , ω , f
- Convergence is decent
- Recovered Elements: 12 (18.8%)
- Hits: 98.2
- Resolution: 32.4 arc seconds
- Log Like: 748
- Many of these elements were perturbed so far the original is no longer even the nearest asteroid!
- Fit quality: 4.5E-4 AU

Search Known Asteroids with Random Initializations

Masters Thesis Conclusions

- Prove that asteroid search over orbital elements works
- Built a working prototype in TensorFlow
- High quality Solar System integration and astrometric directions
- Proof of concept for an automated asteroid search pipeline
- Random initialization not enough, need to intelligent initialization

Progress Since June 2020

New Baby + Pandemic + House Move ≟ Research

- Between a new baby (Ruth, August 2020)
- and pandemic parenting
- and moving from Boston to Newton...
- Research output has been "suboptimal"
- But I have made a fair amount of progress on the unglamorous back end

From Numpy to Database Back End

- Masters Thesis used "default" strategy to manage data
 - Efficient for prototyping, but does not scale for "big data" applications
- Started with 5.7 million detections in early snapshot
- What if we want to merge data from multiple surveys?
 - Pan-STARRS, upcoming Vera Rubin telescope
- Solution: put all the data into a powerful SQL database!

Setting up a SQL Database

- Running an instance of a SQL database is easier than you think
 - Popular variants include MySQL, MariaDB, PostgreSQL and MS SQL Server
- If you a have a Linux computer, it's almost as easy as \$\\$ sudo apt install mariadb-server && sudo apt install mariadb-client

```
michael@Thor: ~/Harvard/kepler-sieve 2021-03-30 14:59:06
$ sudo systemctl status mariadb

    mariadb.service - MariaDB 10.5.9 database server

```

Python Database Connections

- Extracting data from a SQL database into Python is easy
- Pandas DataFrame is familiar to most of us
 - Very similar abstraction to a SQL resultset
 - Easy to go from SQL to Pandas

```
# Create database engine - once for the whole module
db_url: str = f'mariadb+pymysql://{username}:{password}@{hostname}/?local_infile=1'
db_engine: sqlalchemy.engine = sqlalchemy.create_engine(db_url, pool_size=32)

def sp2df(sp_name: str, params: Dict=dict()):
    """Execute a SQL stored procedure and return a DataFrame."""
    sql_stmt = sp_bind_args(sp_name=sp_name, params=params)
    with db_engine.connect() as conn:
    df = pd.read_sql(sql_stmt, conn)
    return df
```

Writing to SQL databases from Python is harder than it should be

SQL Database 101 by Example

Table Descriptions and Sizes

Table Name	Engine	Row Count	Data Length	Index length	Description
■ AsteroidElements	<u>Aria</u>	3,595,918,656	291G	109G	Keplerian orbital elements (a, e, i, Omega, omega, f) for all known asteroids computed in rebound using the planets as massive bodies and initial conditions from DE435 at MJD 59000.
■ Asteroid Vectors	<u>Aria</u>	3,595,918,656	263G	109G	State vectors (position and velocity) for asteroids computed in Rebound using the planets as massive bodies and initial conditions from DE435 at MJD 59000.Initial conditions for aster
■ SkyPatchDistance	<u>Aria</u>	1,861,084,200	57G	74G	Distance bewteen two SkyPatch cells; only cataloged for neighbors that are reasonably close.
■OrbitalElements_DE435	<u>Aria</u>	253,440,352	20G	6.2G	State vectors (position and velocity) for Solar Systems bodies computed in rebound using the planets as massive bodies and initial conditions from DE435 at MJD 59000. Includes reco
■ StateVectors_DE435	<u>Aria</u>	254,160,353	18G	6.2G	State vectors (position and velocity) for Solar Systems bodies computed in rebound using all the massive bodies from the DE-435 integration with initial conditions at MJD 59000. Inclu
■ SkyPatchGridDistance	<u>Aria</u>	310,180,328	12G	12G	Distance bewteen two SkyPatchGrid cells; only cataloged for neighbors that are reasonably close.
■ RawDetection	<u>Aria</u>	158,843,412	9.7G	5.6G	Detections of possible asteroids across multiple data sources, as quoted in RA/DEC by original source.
■ SkyPatch	<u>Aria</u>	25,165,824	3.6G	1.1G	Collection of discrete patches of the sky corresponding to a cube in which the unit sphere is inscribed.
■OrbitalElements_Planets	<u>Aria</u>	43,200,010	3.5G	1.1G	State vectors (position and velocity) for Solar Systems bodies computed in rebound using the planets as massive bodies and initial conditions from DE435 at MJD 59000.Includes record
■ StateVectors_Planets	<u>Aria</u>	47,520,011	3.5G	1.2G	State vectors (position and velocity) for Solar Systems bodies computed in rebound using the planets as massive bodies and initial conditions from DE435 at MJD 59000. Includes reco
■ SkyPatchGrid	<u>Aria</u>	4,194,304	696M	43M	SkyPatchGrid describes the 4N^2 square grid cells on one major face
= Counter	<u>Aria</u>	16,777,216	675M	144M	Utility table - enables a SQL query to emulate a for loop. Data type is signed integer; range is non-negative integers up to 2^24.
■ IntegrationTime	<u>Aria</u>	10,713,601	442M	359M	Distinct time stamps at which MSE integrated positions of solar system bodies are available.
AsteroidElement_Ref	<u>Aria</u>	958,695	124M	32M	Orbital elements of asteroids as of reference dates; used to initialize integrations. Primary for these elements is the Sun, NOT the Solar System Barycenter! See https://rebound.readthed
■CounterSigned	<u>Aria</u>	2,097,151	84M	29M	"Utility table - enables a SQL query to emulate a for loop. Data type is signed integer; range is non-negative integers up to 2^24.";
■ Asteroid	<u>Aria</u>	958,724	46M	33M	Census of all known asteroids including reference to KS.Body table. Orbital Elements stored separately.
■Body	<u>Aria</u>	958,809	38M	17M	Solar System bodies used in the Kepler Sieve application.
■ Detection	<u>Aria</u>	676,053	38M	18M	Detections of possible asteroids across multiple data sources; enriched with unit direction and SkyPatch.
■ DetectionTime	<u>Aria</u>	216,702	24M	9.8M	Time at which one or more detections were made an observatory. Cartesian position and velocity includes topos adjustment.
■ DetectionTimeSlice	<u>Aria</u>	165,284	6.8M	12M	Time at which one or more detections were made an observatory. Cartesian position and velocity includes topos adjustment.
■ DailyTime	<u>Aria</u>	37,201	1.5M	1.3M	Distinct time stamps at sampled once per day.
■ Minutes	<u>Aria</u>	1,440	72K	32K	Enumerate the 1440 minutes in a day to support linear interpolation in queries.
■ BarycenterWeight	<u>Aria</u>	438	32K	24K	Weighting factors for bodies in collections.
■ BodyCollectionEntry	<u>Aria</u>	438	32K	32K	Members of body collections.
■ MassiveBody	<u>Aria</u>	354	24K	16K	Mass of heavy objects included in DE 435 integration, sources from technical comments.
■ BodyCollection	<u>Aria</u>	16	16K	32K	Collections of bodies used in solar system integrations.
■ BodyType	<u>Aria</u>	6	16K	24K	Types of Solar System bodies.
= CubeEdge	<u>Aria</u>	12	16K	24K	The 12 edges of a cube characterized by the pair of vertices sorted in ascending order.
■CubeEdgeVertex	<u>Aria</u>	24	16K	16K	Relate a cube edge to a cube vertex if the vertex is one end of the edge.
■ CubeFace	<u>Aria</u>	6	16K	24K	The six faces of a cube described as the index of the constant axis and its value.
= CubeFaceEdge	<u>Aria</u>	24	16K	24K	Relate a cube face to a cube edge if the edge is on the perimeter of the face.
■CubeFaceNeighbor	<u>Aria</u>	6	16K	16K	Relate a cube face to its four neighbors based on the direction of approach.
■ CubeFacePair	<u>Aria</u>	24	16K	16K	Each pair of distinct cube faces that are connected by an edge
= CubeVertex	<u>Aria</u>	8	16K	24K	The eight vertices of a cube where each coordinate is at +/- 1.
■ DataSource	<u>Aria</u>	1	16K	40K	Data sources for asteroid detections.
■ Observatory	<u>Aria</u>	2	16K	40K	Astronomical observatories and their position on earth.
■ Orbital Elements	<u>Aria</u>	0	8K	8K	State vectors (position and velocity) for Solar Systems bodies computed in rebound using the planets as massive bodies and initial conditions from DE435 at MJD 59000.
■ PrimaryBody	<u>Aria</u>	0	8K	8K	Default primary for each body when integrated in the Planets or DE435 collections. Almost always the Sun except that the primary of the Moon is Earth.
■ StateVectors	<u>Aria</u>	0	8K	8K	State vectors (position and velocity) for Solar Systems bodies computed in Rebound using the planets as massive bodies and initial conditions from DE435 at MJD 59000. Not limited to

What Next?

Enrich ZTF Detection Data

- Compute direction $u_{obs} = (u_x, u_y, u_z)$ for every detection
- Assign integer SkyPatchID to every detection
- Associate every ZTF detection with nearest known asteroid
- Compute the exact position for every candidate asteroid that might be the nearest to each detection, then take the closest one

Generate Candidate Elements from Tracklets

- A set of orbital elements has 6 degrees of freedom
- One detection has 2 D.O.F., RA and DEC; a tracklet has 4
- To discover new asteroids, probably need some way to generate a 2D space of candidate orbital elements consistent with a single tracklet
- Current idea: provisionally assign r (distance from sun to object) and r'; these follow a well behaved distribution and are easy to work with

Mille Grazie: Thank you for Your Attention!

Appendix: Asteroid Search Techniques

Search Techniques I: Uniform Scale, Gradient Clipping and Independent Weights

- Control variables on uniform scale in [0, 1]
 - e.g. a = a_min x exp(a_ x log(a_max / a_min)); a_ trainable in [0,1]
- Clip gradients by norm; max $| | Grad \mathcal{L} | | = 1$
 - would be better to do this elementwise, but requires custom class
- Track log likelihood and hits for each candidate element before summing them in the objective function
- Revert changes only on elements that got worse during an episode
- Weight log likelihood for each element in batch independently

$$\mathcal{L} = \sum_{i=1}^{b} w_i \cdot \mathcal{L}_i$$

- equivalent to controlling 64 learning rates independently
- reduce learning rate on an element when it overshoots

Search Techniques II: Mixture vs. Joint Mode, Encouraging Convergence

- Joint mode: learn all parameters jointly
- Mixture mode: only learn N_h , R, τ
- Learning rate: 2⁻¹² in mixture mode vs. 2⁻¹⁶ in joint mode
- Modified objective function in mixture mode

$$\mathcal{L} = \sum_{i=1}^{b} w_i \cdot \frac{\mathcal{L}_i}{R_i^{\alpha} \cdot \tau_i^{\beta}}$$
